TITLE: Interrupted pressing of intricate shapes from VK powders and their sintering

CITED SOURCE: Tr. Kuybyshensk. aviats. in-t, vy+p. 16, 1963, 195-199

TOPIC TAGS: intricate shape pressing, powder pressing, powder shape sintering, flanged part pressing

TRANSLATION: A single duplex pressing of intricate-shape flanged parts renders the fabrication of equally dense parts difficult. Usually, the flange edges cannot be pressed because of a difference between the height of the main section of the article and the height of the flange, and hence, a difference in the motion of the top and bottom punch. A method is proposed for a separate, two-step pressing of flanged parts in which the bottom punch is used first to press the body (the top punch is used as the bottom of the die). The top punch is then removed, the upper layer of the compacts is broken up, a weighed amount of powder is added for molding the flange and is pressed with the top punch with the bottom punch being fixed.

TITLE: All-union conference technical progress and specialization of the forging-stamping production

SOURCE: Vestnik mashinostroyeniya, no. 5, 1966, 86

TOPIC TAGS: metallurgic conference, metal forging, metal stamping

ABSTRACT: An All-Union Scientific and Technical Conference, sponsored by the State Committee for Machine Building, the Scientific and Technical Society of the Machine Building Industry, and the Khar'kovskiy Sovmarkhoz, was held in Khar'kov in November, 1965. More than 300 delegates attended.

The conference was devoted to questions of further development in forging and stamping production by automation and mechanization of technological processes, and organization of completely mechanized sections, shops, and plants for the production of forgings and stampings.

V.A. Masson (Committee for Machine Building) reported on basic trends in the development of specialization in forging and stamping production and noted the insufficient concentration and specialization of forging production at the present time.

N.T. Deodriyev, ENIKMASH (Experimental Scientific Research Institute of Forging and Pressing Machine Building) reported on the status of technology and equipment for specialized production of forging and stampings and the work of the institute on development of new machines and technological processes.

A.M. Grassik (Toploproyekt) reported on the variety of forging heating furnaces developed by the institute and made recommendations for their introduction under different production conditions.

A.M. Mansurov (Giproavtoprom), V.E. Karminskiy (Giprotraktorosel'khoz'mash) and A.E. Balin (PTNIL, Gor'kiy) reported on the basic principles of designing and plans for several specialized forging workshops for the production of parts.

R.V. Pikhtovnikova (Khar'kov Aviation Institute) reported on the organization of specialized sheet stamping productions using explosives, on the equipment of which large-sized articles such as bottoms, panels, etc., can be very effectively made. S.M. Khamara (Khar'kov Polytechnical Institute), N.P. Vedeneyev, Ye. G. Sazhin and Ye.Ya. Sokol'skiy (Eighth /sic/ State Bearing Plant) spoke about the construction, organization, specialized production and exploitation of a hard-alloy stamping tool.

The following topics were dealt with in other reports: reconstruction of the furnace unit at the Khar'kov Turbine Plant and organization of specialized units at ZIL; "Svet shakhtana" Plant (Khar'kov) on the process of making sprocket wheels at the "Gomsel'mash" Plant, use of electrohydraulic and magnetic impulse stamping, and development of specialized production of forgings, etc.

TITLE: On Alluvial Deposits in the Lower Carboniferous of the Western Parts of the Donets Basin. (Ob allyuvial'nykh otlozheniyakh v nizhnem karbone zapadnykh rayonov Donbassa, Russian)

PERIODICAL: Doklady Akademii Nauk SSSR, 1957, Vol 113, Nr 3, pp 664-666 (U.S.S.R.)

ABSTRACT: A short survey is given on the data of the determination of alluvial formations in the lower carboniferous formations in the region of Petropawlowsk-Pawlograd, the SW continuation of the Donetz basin. Investigations were based on the lithologo-facial method. The material investigated was a sample obtained by wildcat drilling. As a result of investigations it may be said that at the time of the formation of carboniferous layers the more remote parts of the shore were in the North and NE, whereas in the South and SW were the more shallow parts of the coast. Behind this coast was the continent which was the main source of detritus. Therefore, rivers at that time flowed from South and SW towards North and NE. (2 Illustrations and 4 Slavic References).

ACC NR: AP7002442

the coating materials are given; these were high temperature steels containing high carbon contents (0.72-3.10%) and alloyed with Si, Mn, Cr, W, Ni, V, and Ti. Hot hardness data were given as a function temperature, before and after tempering, for the 6 and 10 mm coatings. At 20°C all of the materials had a high hardness (R_c 50-60). As the temperature increased the hardness decreased, especially at about 500°C. The hardness value above 500°C was an indication of the red hardness of the coating materials. After tempering, some materials such as 5Kh4V3FT, 5Kh4V3FTs, U20Kh17T, and U20Kh17T1 dropped in hot hardness to as low as 32-40 R_c at 650°C. The two steels U30Kh25N4S4V8 and U25Kh23N4S3G were the most resistant to tempering. The following are listed in decreasing order of hot hardness and tempering resistance: U30Kh25N4S4V8, U25Kh23N4S3G, 3Kh2V8, Kh12VF, U20Kh17T1, U20Kh17T, 5Kh17T, 5Kh4V3FT, 5Kh4V3FTs, and 5Kh4V3F. TITLE: Biochemical changes in a synchronous culture of *Azotobacter vinelandii*

PERIODICAL: Akademiya nauk SSSR. Doklady, v. 141, no. 3, 1961, 740 - 743

TEXT: The developmental cycle of a cell was studied in an *Azotobacter vinelandii* culture with synchronous cell division (Refs. 4 and 5, see below). This culture is most suitable for studies on biochemical changes of important macromolecular substances and their preliminary stages of synthesis in the vital process of every cell. Synchronization (two cycles) was caused by the action of low temperatures on a culture contained in a reaction vessel of 45 liters (Refs. 4 and 5, see below). As soon as $\sim 2 \cdot 10^7$ cells per milliliter of nutrient medium were reached, the culture was cooled down to 5 - 7°C within 20 - 25 min by flowing water. For 1 hr it was kept at this temperature. Vapor was passed through to elevate the temperature rapidly to 30°C. The cells were counted in a Goryayev chamber [Abstracter's note: Chamber not stated.], and the biomass was nephelometrically measured. Samples of

3.0 - 3.5 liters each were taken out for analytical studies. (0) Initial sample; (I) after cooling; (II) before first division; (III) after first division; (IV) during second lag phase; (V) before second division; (VI) in the middle of second division; (VII) at the end of second division, and (VIII) before third division. Nitrogen and phosphorus compounds were fractionated and quantitatively determined by methods described earlier (A. N. Belozerskiy et al., *Mikrobiologiya*, 26, 409 (1957); G. N. Zaytseva et al., *Mikrobiologiya*, 28, 675 (1959); A. N. Belozerskiy et al., *Biokhimiya*, 24, 1054 (1959)). After fractionation, mononucleotides, RNA, and DNA, were spectrophotometrically measured by $C\Phi-4(SF-4)$. The DNA amount was chemically determined according to K. Burton (Ref. 3, see below). The accumulation of the total nitrogen per 100 milliliters of nutrient medium, and biomass increase were found to take place almost simultaneously. Since the total nitrogen of the culture increases exponentially, the nitrogen fixation is also assumed to proceed exponentially. Calculated for the first division cycle of the whole culture, protein nitrogen shows a slight tendency to increase by steps. Calculated for one cell, this tendency becomes evident: The protein-N amount increases at the end of each lag phase and decreases noticeably immediately after division. The amount of

Card 2/4

S/020/61/141/003/019/021
B103/B101

NH₂ nitrogen of amino acids, however, considerably decreases before cell division. This is probably due to an intense consumption of free amino acids in the protein synthesis. The considerable increase of amino acids during cell division is probably due to a slow protein synthesis at this stage. It was also found that DNA synthesis during synchronization took place periodically, i. e., largest amounts of DNA were accumulated before cell division. After division, it is reduced during two cycles in exact harmony with the rhythm of cell division. With RNA, these fluctuations are less evident and only noticeable during the first cycle. Calculated per cell, this periodicity is very clear and indicates the participation of RNA in cell mass synthesis, especially that of proteins. During cell division, DNA is not synthesized, and as far as there is an RNA synthesis during that period it proceeds very slowly. DNA synthesis in *Azobacter* cells is assumed to take place shortly before cell division. The amount of acid-soluble mononucleotides increases rapidly before each cell division, then a sudden drop follows. This holds especially for diphosphates and triphosphates of nucleotides which increase and decrease together with nucleic acids. Other phosphorus compounds also have cyclic fluctuations. During cell division, polyphosphates insoluble in acids decrease, whereas acid-

Card 3/4

Biochemical changes in a...

S/020/61/141/003/019/021
B103/B101

soluble ones increase. High-molecular polyphosphates are assumed to be reduced to low-molecular fragments and orthophosphate to provide phosphorus and energy for cell division. Phosphoric esters of sugar show no periodic synthesis. Polysaccharide increases exponentially. Phospholipids are cyclically synthesized. N. D. Iyerusalimskiy, Corresponding Member AS USSR, is thanked for his interest in the work. There are 4 figures and 12 references: 4 Soviet and 8 non-Soviet. The three most important references to English-language publications read as follows: Ref. 4: A. Campbell, Bacteriol. Rev., 21, 261 (1957); Ref. 5: O. H. Scherbaum, Ann. N. Y. Acad. Sci., 90, 565 (1960). Ann. Rev. Microbiol., 14, 283 (1960); Ref. 8: K. Burton, Biochem. J. 62, 315 (1956).

TOPIC TAGS: acetylenic oxide, acetylenic halohydrine, amino alcohol, epoxide, acetylene compound, condensation reaction, dimethylamine

ABSTRACT: The previously unreported acetylenic halohydrines (Ia—Ic) were obtained in 65–85% yield from 3-ethyl-3-penten-1-yne, 3-propyl-3-hexen-1-yne, and 3-butyl-3-hepten-1-yne via the corresponding Iotsich reagents. Treatment of Ia—Ic with KOH in ether yielded the previously unreported epoxides IIa—IIc. Condensation of IIa—IIc with dimethylamine and diethylamine yielded the previously unreported amino alcohols IIIa—IIIc and IVa—IVc:

Improvement of quality of processed cheese. A. Khmylev (Meat and Dairy Ministry, Moscow). *Molok. Khleb. Pirog.* 13, No. 7, 22-3 (1952).--Common difficulties in production of processed cheese and its handling are briefly discussed. Use of NaH_2PO_4 , which can lead to development of bitter taste and cause corrosion of the wrapping foil and use of Na_2K tartrate which causes deposition of crystals of the acid within the product are mentioned. When up to 20% NaH_2PO_4 was used, the cheese was of high taste quality. G. M. Kosolapoff
